2 DAYS HANDS-ON COURSE

AUTOTRANSPLANTATION OF TEETH

Dentistry has undergone a major change in recent years during which its focus has swayed from material and technological advances to healing and biology. This shift can be observed in endodontics, restorative dentistry or oral surgery. But at the pinnacle of it stands periodontology. Surprisingly, a rather old method of autotransplantation of teeth, has not been used in a more extensive manner, although its potential is immense and we are still looking for its possible applications and limits. Due to a comprehensive treatment protocol and due to growing understanding of biologic processes the survival and success rates have become well acceptable. This treatment modality offers absolutely unique ways of replacing missing teeth or saving teeth considered absolutely hopeless just a few years ago.

The hands on course has been conceived to allow participants to understand basic principles of periodontal and pulpal healing and their application in the surgical and follow-up protocol. Two different clinical situations will be trained on pig jaws - transplantation of a tooth into a fresh extraction socket, transplantation into a healed ridge.

An irreplaceable part of the course is a thorough discussion of possible complications and their clinical management presented on numerous case reports.
